In this post, I share 12 of the most common Photoshop shortcuts. Some of these shortcuts (such as cmd + z for undo) are things that beginners often forget to know. Filter Stack Photoshop has many features for fine-tuning images, but most of the time, when you start editing an image, you need to start from scratch. To start from scratch, you need to create a new layer and set all the settings to zero. This wastes time and resources. Instead, create a new layer called "Filters" and load filters from a "Stack." "Filters" is an empty layer. If there are too many filters, you can select "Filter" from the Layers menu and choose "New Filter Stack." Or you can use the keyboard shortcut: Shift + F5 (or Ctrl + F5). Photoshop shows the Filters stack while you are editing. The Filters stack holds the history of filter settings for the last few images you edited. You can also use the keyboard shortcut: cmd + Shift + F5 (or Ctrl + Shift + F5). When you click on an image with the Filters stack active, Photoshop automatically reloads all the filters from the stack. Click on an image with the Filters stack active and then click "delete" or press cmd + backspace to reload filters from the stack. Filters from Stacks Using a filter stack is not only faster than starting from scratch. You can also fine-tune the filter settings and adjust them to your needs. The Filters stack is also used to add a new filter while in the Filters Stack Editor. Click on the Filters tab and then click the New button. Then, use the following keyboard shortcuts to switch the image to another filter stack: Shift + F5: go back to the Filters Stack. Ctrl + Shift + F5: go to the next stack. Ctrl + Shift + F6: go to the last stack. You can also use the keyboard shortcut: cmd + Shift + F5 (or Ctrl + Shift + F5). Cut Tool The Cut tool works exactly like the tool you use to cut the image. You can use the tool to delete pixels, duplicate pixels or move pixels to a new location. The Cut tool is used to cut out a portion of an image and then resize the image. It a681f4349e

World Journal of Ecology International Journal of Ecology Publications Abstract The genetic similarity between populations from a river drainage may be so high that the river drainages are a single population and should be considered as a single population for all statistical analyses. Nevertheless, except when conducting cladogram analyses, it is always preferable to treat the river drainages as separate populations, especially because population structure may influence fitness and ecological effects. In this study, the effect of population size on the structure of populations from natural populations of the pikeminnow (*Ptychocheilus*) japonicus – the Japanese small-mouthed carp – in the Pearl River was investigated. A single locus, ca. 1200 bp long, was analyzed by means of intersimple sequence repeat (ISSR) analysis. Two loci, ca. 780 and 660 bp, were also analyzed with respect to their polymorphism and potential usefulness in determining population structure in samples from the Pearl River. Only the shorter locus was polymorphic at significant levels. The more polymorphic locus revealed only one allele in 10 populations from the Pearl River, with only three exceptions for which it was detected twice. This population-size effect suggests that the Pearl River populations are large. I detected two genetically distinct groups among the Pearl River populations with respect to the ca. 780-bp ISSR locus. The first group consists of the populations of the Pearl River from the southern part of the drainage. The second group includes the Pearl River populations from the western part of the drainage. These two groups are genetically different from each other, and their average allelic frequencies are significantly different. This study provided a population-structure analysis in the Pearl River that was based on the association between genetic distance and geographical distance. Based on the results of the present study, the genetic dissimilarity in the Pearl River decreases as geographical distance increases. This may suggest that the breeding populations of the Pearl River originate from a few large freshwater refugia distributed in the Pearl River catchment area. A significant positive correlation was detected between genetic similarity and geographical distance (Pearson’s correlation $r = 0.54$, $p = 0.005$), providing evidence for the importance of hydrologic factors in maintaining natural populations. The present results also indicate that the extent of genetic dissimilarity in the Pearl River is smaller than that in other rivers. Citation The Japanese small-mouthed carp *Ptychocheilus japonicus* is an endemic freshwater
